

Epigenetic memory in Norway spruce

48e5d53e854448e5d53e854448e5d55e854448e5d55e8544448e5d53e854448e5d53e854448e5d53e854448e5d53e854488e5d53

- The temperature during zygotic embryogenesis and seed maturation shifted the growth cycle program of the embryos resulting in significant and long lasting phenotypic changes in the progeny (Johnsen et al., 2005; Skrøppa et al. 2007; Kvaalen & Johnsen, 2008; Yakovlev et al. 2012)
- The timing of the following phenologic traits was affected:
 - dehardening and bud burst in the spring
 - leader shoot growth cessation in the summer
 - bud set and cold acclimation in the autumn
- The significant global transcriptomic changes were found during development of somatic embryos of Norway spruce with the same genotype under different cultivation temperatures (Yakovlev et al. 2014):
 - clear trend of increasing of the number of upregulated genes with increasing of temperature
 - nearly half of the genes related to epigenetic regulation were differentially expressed at different growing temperatures (DNA methyltransferases, DNA demethylases, DCL1-like, Argonauts, etc.)

Summary	
•	Expression of DNA is controlled by epigenetic markers including DNA methylation, histone modifications and ncRNAs
•	siRNAs contribute to epigenetic programming
•	Epigenetic programming silences transposons and controls the timing of many genes that control plant development
•	All epigenetic mechanisms shown to be involved in stress response and adaptation
•	Epigenetic systems may act as the conduit for environmental cues initiating short- or long-term changes in gene expression in response to stress.
•	It is very likely that epigenetic variation contributes to the adaptation potential of plants and, like genetic diversity, is under selection by environmental conditions
